Abstract

We describe NSAK as an embedded, modular, open source, scenario-based network sniffing and security framework. We provide an overview of the system design, emphasizing the functionality of a Swiss Army Knife in a networking context. The attack scenario includes drills that configure or target a specific task to observe or open an attack vector in the system. NSAK is based on a core backend part that manages specific environments, scenarios, and drills. The whole concept is based on containerization, where each container builds or prepares a scenario that can be triggered in a network environment. In the analogy of the Swiss Army Knife, the right knife with the proper drills for the necessary task can be selected. Modularity comes into play when a drill is selected across multiple scenarios.

Keywords Network intrusion detection, Network Monitoring, Red/Blue Team

Rules to apply

One-paragraph summary of the entire study – typically no more than 250 words in length (and in many cases it is well shorter than that), the Abstract provides an overview of the study.

Mit Regeln von Abstract gegenchecken und querlesen

Inhalt Abstract – Hintergrundinformationen wie Ausgangslage, Relevanz, Forschungskontext in ein bis zwei Sätzen zusammenfassen. – Fragestellung und Ziel explizit formulieren. – Die wichtigsten Eckpunkte zum methodischen Vorgehen angeben, bei empirischen Studien auch Angaben zu den Daten wie etwa die Charakteristika der Stichprobe. – Im Hauptteil des Abstracts die relevanten Ergebnisse und deren Bedeutung mit wichtigen Kennzahlen aufführen (ca. zwei Drittel des Abstracts). – Mit wichtigen Schlussfolgerungen oder Anwendungsmöglichkeiten das Abstract abrunden. – Das Abstract enthält keine Quellenverweise

1 First Part Thesis: Evaluation

Introduction

The combination of red team activities and blue team observation techniques is widely adopted within the cybersecurity community. While the red team focuses on emulating adversarial behavior, the primary objective of the blue team is to detect such activities through non-invasive monitoring and analysis of system behavior [?].

Braucht es

sind alle
Punkte erfüllt

As the economic and operational costs of launching cyberattacks continue to decrease due to AI automation [?], the need for continuous surveillance and Zero Trust Architecture is rising. One approach to reduce operational security costs is to adopt multiple modular frameworks that can be easily extended, configured, and executed continuously in a controlled manner [?].

The threat emulation frameworks introduced by Zilberman et al. evaluate multiple attack phases, including lateral movement, persistence, and attack execution. The Network Swiss Army Knife focuses on containerized, orchestrated scenarios that execute specific attack drills in a controlled environment. Future extensions will focus on enriching the assessment layer by systematically capturing and evaluating defensive responses of multiple scenarios.

This proof of concept comprises the design and implementation of a modular, isolated open-source security framework that focuses on extensibility and the controlled execution of attack-based scenarios.

The objective of this work is to investigate whether such a framework can provide a flexible, extendable, and safe foundation for modular security testing in a network environment.

2.2 Einleitung Die Einleitung führt einerseits zum Thema hin (Ausgangslage), und informiert andererseits darüber, warum (Fragestellung/Problem) und wozu (Ziel/Zweck) es die Arbeit gibt sowie ggf. wie sie zustande gekommen ist (methodisches Vorgehen). Die Einleitung kann je nach Umfang und Thema mit oder ohne Unterkapitel verfasst werden. Sie umfasst ca. 5–10 Einen Überblick über die Kapitel der Arbeit gibt es höchstens bei sehr langen Arbeiten (beispielsweise Masterarbeit). Die Ausgangslage beschreiben – Relevanz: Warum ist dieses Thema überhaupt bedeutsam? Schon hier gilt es, nicht einfach etwas zu behaupten, sondern Fakten und Aussagen mit Fachliteratur zu belegen. – Aktualität: Gibt

es einen aktuellen Bezug? – Zusammenhang: Wie lässt sich das Thema einordnen? In welchem fachlichen Kontext steht die Arbeit? – Forschungsstand: Was ist schon erforscht? Gibt es bereits Untersuchungen? (Ist-Zustand und Zusammenhang mit dem eigenen Thema.) Je nach Art und Umfang der Arbeit gibt es zum Wissensstand ein separates Kapitel (siehe 2.3). – Wenn vorhanden externe Auftraggeber, Auftraggeberinnen: Wer sind die beteiligten Partnerinnen oder Stakeholder? – Den Kurs bzw. das Modul, in dem die Arbeit entsteht, erwähnt man auf dem Titelblatt (siehe 4.1). 8 Das Problem und das Ziel darstellen – Zweck der Arbeit: Welche Aufgabe, Herausforderung, welches Problem soll gelöst werden? Warum sollte man die Arbeit lesen? – Fragestellung: Auf welche konkrete Hauptfrage (evtl. mit konkretisierenden Unterfragen) soll im Schlusskapitel eine fundierte Antwort gegeben werden? Ist die Fragestellung genügend eingegrenzt? Gibt es Hypothesen? – Abgrenzung: Wo liegen die Grenzen der Untersuchung (zeitlich, geografisch, thematisch, methodisch, in der Auswahl der Hilfsmittel usw.)? Was wird nicht untersucht? Was kann die Arbeit nicht leisten? – Ziel: Was soll die Untersuchung genau bewirken? Was ist die Absicht hinter der Arbeit? – Erwartung: Was möchte die Arbeit leisten (Nutzen der Untersuchung, Soll-Zustand)? Für welche konkrete Zielgruppe sind die Ergebnisse der Arbeit von Nutzen? Was ist zu erwarten? Was ist nicht zu erwarten? Das methodische Vorgehen andeuten Wie man methodisch vorgeht, wird ausführlich im Methodenkapitel beschrieben (siehe 2.4). Oft erwähnt man aber in der Einleitung bereits in ein bis zwei Sätzen, mit welcher Methode man arbeitet (Literaturarbeit, Umfrage, Entwickeln eines Prototyps, Variantenstudium usw.).

1.1 Current State of Research

Der «Stand der Forschung» beantwortet folgende Fragen:

- Was wurde zum Thema der Arbeit bereits erforscht (Forschungsstand)? – Auf welche Forschungsarbeiten stützt sich die Arbeit ab? – Welche Theorien oder Konzepte sind für die Beantwortung der Fragestellung relevant? – Welche Begriffe müssen definiert werden? – Welche Normen spielen für die Untersuchung eine Rolle

2 Evaluation

2.1 Hardware Selection

2.1.1 Hardware Requirements

The following requirements were defined for the hardware platform used in this project:

- ▶ At least two native Ethernet interfaces for inline packet sniffing
- ▶ Support for 2.5 GbE or higher
- ▶ Onboard Wi-Fi with access point (AP) and monitor mode support
- ▶ Low power consumption suitable for 24/7 operation
- ▶ Compact form factor for laboratory and prototype setups
- ▶ Strong community and software support
- ▶ Affordable cost (below 150 CHF)

2.1.2 Evaluated Boards

Several boards were considered as potential variants. Their main specifications relevant to the project are listed in Table 2.1.

Table 2.1: Comparison of Board Variants

Board	SoC / CPU	RAM / Storage	Ethernet Ports	Power (typ.)	Wireless (on-board)
Banana Pi R3 Mini	MT7986A, Quad-core ARM Cortex-A53 @ 1.3 GHz	2 GB DDR4, 8 GB eMMC, microSD	2 × 2.5 GbE	5–7 W	MT7976C, Wi-Fi 6 (AP/Client/Monitor)
Banana Pi R3	MT7986A, Quad-core ARM Cortex-A53 @ 1.3 GHz	2–4 GB DDR4, eMMC, microSD	1 × 1 GbE, 2 × 2.5 GbE, 4 × 1 GbE	7–10 W	MT7976C, Wi-Fi 6
Banana Pi R4	MT7988A, Quad-core ARM Cortex-A73	4 GB DDR4, NVMe option	4 × 2.5 GbE, 2 × 10 GbE (SFP+)	10–15 W	None (M.2 Wi-Fi module required)
Banana Pi R5	MT7988B, Quad-core ARM Cortex-A73	4 GB DDR4, NVMe option	2 × 10 GbE, 2 × 2.5 GbE	12–18 W	None (M.2 Wi-Fi module required)
Raspberry Pi 4	BCM2711, Quad-core ARM Cortex-A72 @ 1.5 GHz	2–8 GB LPDDR4, microSD	1 × 1 GbE (second via USB dongle)	6–8 W	Wi-Fi 5 (AP-/Client only)
Raspberry Pi 5	BCM2712, Quad-core ARM Cortex-A76 @ 2.4 GHz	4–8 GB LPDDR4X, microSD	1 × 1 GbE (second via PCIe card)	8–12 W	Wi-Fi 5 (AP-/Client only)
NanoPi R76S	Rockchip RK3588S, Octa-core (4× Cortex-A76 @ 2.4 GHz + 4× Cortex-A55 @ 1.8 GHz)	16 GB LPDDR4X / LPDDR5, NVMe (option via M.2)	3 × 2.5 GbE (RJ45)	10–15 W	None (M.2 Wi-Fi 6E module recommended)

Table 2.2: Requirements Fulfillment by Candidate Boards

Requirement	R3 Mini	R3	R4	R5	RPi 4	RPi 5	NanoPi R76S
2 native Ethernet interfaces	✓	✓	✓	✓	✗	✗	✓
RAM > 4GB	✗	✗	✓	✓	✗	✓	✓

Legend: ✓ = Requirement fulfilled, ✗ = Requirement not fulfilled, ▲ = Partially fulfilled / limited

2.1.3 Decision

Based on the defined requirements and the evaluation of alternatives, the **Banana Pi R4** and the **NanoPI R76S** are the most suitable hardware platforms for this prototype implementation.

The Banana Pi R4 offers two native 2.5 GbE interfaces for inline sniffing the board is compact, affordable, and supported by a strong community. In Addition, the two 10 GbE SFP+ ports provide flexibility for extensions as fiber-based packet capturing. A drawback of the R4 is the weaker CPU and a larger size compared to the NanoPI R76S

The NanoPi R76S is more compact and provides up to 16GB of RAM, which is advantageous for memory-intensive processing and buffering tasks. While it lacks built-in Wi-fi, it can be expanded via the M.2 Wi-Fi 6E module. It cannot host both a Wi-Fi card and NVMe SSD simultaneously. Consequently, data storage must be provided via microSD card or external USB SSD

Alternative boards such as the Banana Pi R3 Mini, R3 are limited overall performance. Raspberry PI 4 or 5 offer higher single core performance but were ultimately discarded because they provide only a single native Ethernet interface, requiring external adapters that reduce performance for inline sniffing scenarios.

2.1.4 Hardware Specification

Each environment represents a practical setup in which the NSAK device can be deployed. For traffic analysis, performance testing or security evaluation.

Category I — Inline:

Diagram: Laptop ↔ NSAK device ↔ Router

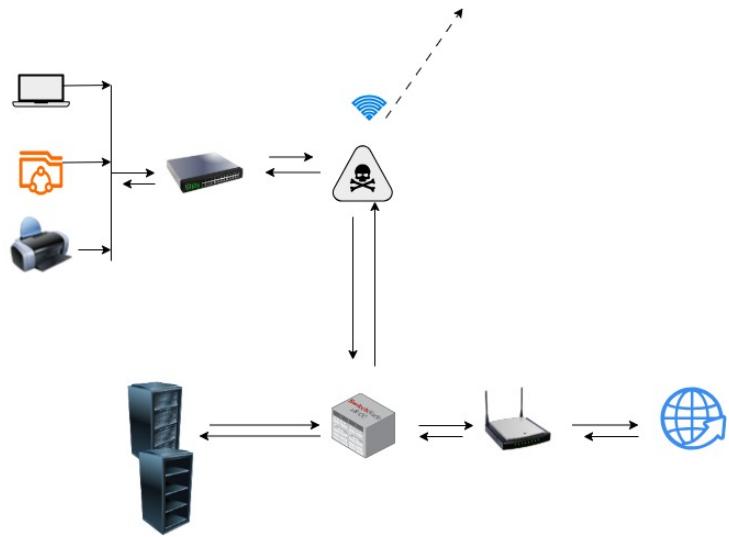

Figure 2.1

Description: Direct inline bridge between a client or switch and router. Used for basic LAN capturing, latency, and throughput testing.

Category II — Wireless:

Diagram: Laptop, Smart Devices, Printer \leftrightarrow NSAK device (inline) \leftrightarrow Router

Figure 2.2

Description: The NSAK device is inline and lets traffic pass but intercepts as Rouge AP and capture data

2.2 Software Selection

2.2.1 Framework Technology Stack

Core / CLI

Programming language: Python
Dependency manager: uv
Virtual environment manager: uv
Package build tool: uv
Linter: ruff
Formatter: ruff
Type checker: mypy
Testing framework: pytest

Dependencies: click: Library for building CLIs
pyyaml: Library for loading, validating and reading yaml files
scapy: Library for red team operations
pre-commit: Package to enforce code quality tools for each commit

2.2.2 System Dependencies

As we leverage the abstraction of OCI containers to run scenarios in an encapsulated environment, we have only a minimal set of system dependencies. All

Describe why we choose this technology, maybe we find references which underline the ease of use and advantages for modularity which are comming with python

Write this section nicer and explain what the advantages are of such a design is, especially in relation to modularity

system dependencies that are required for running a drill or a scenario are installed into the scenario image, during the build process.

Version control: git
Network tooling: iptables (we should switch to nf_tables)
OCI container manager: podman
OCI container orchestrator: podman-compose
Programming languages: python3, python3-pip, uv
Utilities: curl, sudo

3 Architecture and Design

3.0.1 Framework Concepts

This section describes the high-level concepts which can be managed with the NSAK framework.

Overview:

- ▶ Devices
- ▶ Environments
- ▶ Drills
- ▶ Scenarios

I did not think of a specific order, add a short excerpt in the overview list, add a diagram which shows the relation of the concepts

Devices

Environments

Drills

Scenarios

3.1 Use-Cases

Figure 3.1

Figure 3.1 illustrates the use case structure of the proposed NSAK modular framework. The operator interacts with the NSAK primarily through two high-level commands: Build Scenario (UC-01) and Run Scenario (UC-06). During the Build Scenario use case (UC-01), the system builds a scenario container for execution. In complex network infrastructures, additional configuration parameters—such as network interface mappings may be required and need to be provided as build-time arguments (UC-02).

The system loads the selected scenario (UC-03). At this stage, the scenario orchestrates the required drills necessary to perform the intended attack.

The build process concludes with the creation of an OCI-compliant container image (UC-05), which encapsulates the fully configured scenario.

The Run Scenario use case (UC-06) represents an abstract execution phase. In

this phase, the previously built container image is runed, and the configured attack drills are been executed within the containerized environment (UC-08).

Finally, the system performs a cleanup procedure in which all scenario-specific resources, processes and drills are terminated. This step minimizes side effects, reduces system noise, and prevents interference other scenarios that may reuse the same drills.

3.2 Component-diagram

SSH und SystemD aus dem Diagramm nehmen

Figure 3.2

3.3 Sequence-Diagram

Figure 3.3

Figure 3.3 shows the interaction sequence for building, loading, and executing a scenario within NSAK. The diagram focuses on the main modularity concept and describes the orchestration flow between scenarios and drills without interface details, error-handling, and drill or scenario clean-up mechanisms.

The process begins with the operator triggering the build command for a scenario container. During this phase, the selected scenario is loaded and returned as a containerized representation. In the execution phase, the Scenario Manager runs the container image and orchestrates the Drills order. The Drill Manager executes the required drills.

A scenario may contain multiple drills; therefore, the * signalize various drills can be executed from a Drill Manager in one scenario. Each drill is resolved and executed individually, while the Scenario Manager maintains complete control over the scenario lifecycle.

4 Second Part Thesis: Implementation

4.1 Method

4.1.1 Research Approach

This work follows a design-oriented research approach and presents a proof of concept of a modular network sniffing framework named NSAK (Network Swiss Army Knife). The objective is not to introduce a new type of network attack techniques, but to design and implement a modular framework that enables reproducibility and encapsulation in network security systems.

The Swiss Army Knife inspires the conceptual design of the NSAK device: Instead of providing a single-purpose tool, the framework offers multiple small specialized components. that can be used depending on the operation. For the NSAK device, the operational environment is the network. Situations are represented as scenarios, and Individual tools for performing a task are implemented as drills.

The research is primarily based on existing scientific literature, including journal articles, conference papers, and established open source networking tools. The focus lies on system integration, modularization, architectural design, reproducibility, and experimental validation rather than theoretical innovation.

4.1.2 System Design Strategy

The NSAK framework is structured in three main layers: a core backend, a CLI package, and a library package. The NSAK device comprises three components: environments, scenarios, and drills. The library provides reusable, small-component packages that are used by the core's central logic. loads, manages, and executes.

The click CLI provides all the user handling over the command line.

sollen wir das
rausnehmen

From a contributor's perspective, extending the framework requires answering three guiding questions:

- ▶ In which network environment is the NSAK device operating?
- ▶ Which scenario should be executed in that environment?
- ▶ Which drills are required to implement the scenario?

end

4.1.3 Scenario Oriented Orchestration

Scenarios are responsible for orchestrating drills and defining the drill order in which they are executed. Therefore, it needs specific parameters to be passed to the drill. Finally, the scenario is responsible for managing the cleanup process of the drills.

Each scenario is designed to run inside a containerized environment, to ensure reproducibility and isolation. While the scenario runs in the container, the drills it orchestrates execute privileged operations on the host system.

A scenario consists of:

- ▶ a scenario.py file containing the orchestrating scenario
- ▶ a scenario.yaml file describing metadata and dependencies
- ▶ and a README.md file providing configuration, tips, and documentation

4.1.4 Modular Drill-Based Architecture

A drill represents the smallest functional unit within the NSAK framework. Each drill is responsible for a specific task.

A drill consists of:

- ▶ a drill.py file containing the execution and cleanup logic
- ▶ a drill.yaml file describing metadata
- ▶ and a README.md file providing configuration, tips, and documentation

By design, drills are independent, allowing them to be reused across multiple scenarios. This modularity enables flexible composition and contribution while keeping the components focused and straightforward.

4.1.5 Experimental Setup

The experimental setup was conducted on an arm-based embedded system equipped with a wireless interface. The following criteria were used to assess the framework:

- ▶ successful execution of individual drills,
- ▶ correct orchestration of multiple drills within a scenario,
- ▶ and reproducibility of experimental results.

The evaluation demonstrates that the NSAK framework enables structured, modular, and repeatable experimentation in network security research environments.

To evaluate the MITM ARP Scenario, the following test environment is necessary:

Layer 2 network switch and cables

2x Raspberry Pi: Alice (Client) and Bob (Server)

Banana PI R4 or Nano PI: Malcom (NSAK)

Three SD Cards for the operating systems

Further Set Up instructions are provided in the README.md

The evaluation of the Rogue Access Point scenario requires a controlled test environment consisting of a gateway host system, an embedded NSAK device (NanoPi or Banana Pi R4), and multiple Wi-Fi client devices, including tablets, laptops, or smartphones.

4.1.6 Delimitation

This work does not aim to evaluate attack success rates in real-world environments. The focus is limited to architectural design and functional validation.

4.1.7 Project Management

The development process used GitLab for version control and issue tracking. An issue board was used to structure development tasks, track progress, and enable the project for future contributions and further development. This approach improves traceability and enables the review of design decisions in the repository.

4.2 Implementation

4.3 Conclusion

Declaration of Authorship

I hereby declare that I have written this thesis independently and have not used any sources or aids other than those acknowledged.

All statements taken from other writings, either literally or in essence, have been marked as such.

I hereby agree that the present work may be reviewed in electronic form using appropriate software.
